

INTEGRATED CIRCUIT DEVICES INCLUDING A MIM CAPACITOR

RELATED APPLICATION

10 This application claims priority from Korean Application No. 2002-78905, filed December 11, 2002, the disclosure of which is hereby incorporated herein by reference.

BACKGROUND OF THE INVENTION

15 The present invention relates to integrated circuit devices and, more particularly, integrated circuit devices including capacitors and methods for manufacturing such integrated circuit devices.

As the integration density of integrated circuit devices has increased, it has become more difficult to obtain a desired capacitance in a conventional Metal-
20 Insulator-Semiconductor (MIS) capacitor, for example, due to a low k-dielectric layer formed between a dielectric layer and a silicon layer. An alternative to an MIS capacitor is a metal-insulator-metal (MIM) capacitor.

FIG. 1 is a cross-sectional diagram illustrating an integrated circuit (semiconductor) device including a conventional MIM capacitor coupled to a
25 transistor. As shown in FIG. 1 a first transistor includes a gate 13a, a source 15, and a drain 17a formed in an integrated circuit substrate 11. A second transistor includes a gate 13b and a drain 17b formed in the integrated circuit substrate 11. The second transistor also includes the source 15.

The drain 17a of the first transistor is connected to a lower electrode 21 of a
30 MIM capacitor via a conductive pattern 19. A dielectric layer 23 and an upper electrode 25 of the MIM capacitor are formed on the lower electrode 21. The lower electrode 21 and the upper electrode 25 are conductive metal layers. An

interconnection layer **27** is formed on and connected to the upper electrode **25** of the MIM capacitor.

The drain **17b** of the second transistor is connected to an upper interconnection layer **33** via the conductive pattern **19** and interconnection layers **29** and **31**. While 5 not shown in **FIG. 1**, the interconnection layer **27** may also be connected to the upper interconnection layer **33**. Also shown in **FIG. 1** are insulating layers **35**, **45**, **55**, and **65**.

One limitation on the performance of the MIM capacitor illustrated in **FIG. 1** is the insufficient distance between the interconnection layer **27** and the lower 10 electrode **21**. As this distance is reduced, an undesirable level of parasitic capacitance may develop, which parasitic capacitance may adversely affect the characteristics of the MIM capacitor. Problems become more severe when the thickness of the insulating layers is reduced, because parasitic capacitance of the device is generally inversely proportional to the thickness of the insulating layer.

15 **FIG. 2** is a graph illustrating a simulation of the influence of parasitic capacitance for different thicknesses of an insulating layer, such as the insulating layer **55**. As illustrated in **FIG. 2**, as the thickness of the insulating layer decreases, the parasitic capacitance increases in a non-linear manner.

Thus, for a conventional integrated circuit device including a MIM capacitor 20 as illustrated in **FIG. 1**, an increase in parasitic capacitance between the interconnection layer **27** and the lower electrode **21** may degrade and/or reduce the stability of the characteristics of the MIM capacitor. In addition, the variability of the parasitic capacitance based on process variables such as the thickness of an insulating layer may increase the difficulty of forming MIM capacitors with stable 25 characteristics.

SUMMARY OF THE INVENTION

Embodiments of the present invention include integrated circuit devices including an integrated circuit substrate and a conductive lower electrode layer of a 30 Metal-Insulator-Metal (MIM) capacitor on the integrated circuit substrate. A dielectric layer is on the lower electrode layer and a conductive upper electrode layer of the MIM capacitor is on the dielectric layer. A first intermetal dielectric layer is on the upper electrode layer. The first intermetal dielectric layer includes at least one via

hole extending to the upper electrode layer. A first conductive interconnection layer is on the at least one via hole of the first intermetal dielectric layer. A second intermetal dielectric layer is on the first intermetal dielectric layer. The second intermetal dielectric layer includes at least one via hole extending to the first conductive
5 interconnection layer and at least partially exposing the at least one via hole of the first intermetal dielectric layer. A second conductive interconnection layer is provided in the at least one via hole of the second intermetal dielectric layer that electrically contacts the first conductive interconnection layer.

In other embodiments of the present invention, the first conductive
10 interconnection layer is a landing pad type independent interconnection layer that connects the second conductive interconnection layer to the upper electrode. The dielectric layer may have a thickness between the lower electrode layer and the upper electrode layer greater than the thickness of the dielectric layer in other regions of the device. The lower electrode layer may contact an impurity region of the integrated
15 circuit substrate, such as a drain of a transistor device.

In further embodiments of the present invention, the device further includes an insulating pattern of the first intermetal dielectric layer formed between the upper electrode and insulating layer(s) of the first intermetal dielectric layer. The insulating pattern may be formed only on the upper electrode. The insulating pattern between
20 the upper electrode and the first intermetal dielectric layer may be selected from the group consisting of an oxide layer, a nitride layer, an fluorine-doped silicate glass (FSG) layer, an organo silicate glass (OSG) layer, a silicon carbide (SiC) layer and combinations thereof. The insulating pattern may be directly on the upper electrode and the second intermetal dielectric layer may be directly on the first intermetal
25 dielectric layer.

In other embodiments of the present invention, the landing pad type independent interconnection layer is formed to a thickness of about 0.1 μm to about 2 μm . The at least one via hole of the first intermetal dielectric layer may be a plurality of via holes separated from each other and the at least one via hole of the second
30 intermetal dielectric layer may be a plurality of via holes separated from each other. The landing pad type interconnection layer may be formed to the same height as the first intermetal dielectric layer. The first intermetal dielectric layer may include a

trench having a diameter greater than a diameter of at least one of the plurality of via holes and a depth less than a depth of at least one of the plurality of via holes.

In further embodiments of the present invention, the dielectric layer has a thickness between the lower electrode layer and the upper electrode layer greater than 5 the thickness of the dielectric layer in other regions of the device. The thickness of the dielectric layer in the other regions may be from about 0.01 μm to about 0.1 μm .

In other embodiments of the present invention, the device further includes a transistor having a source, a drain and a gate formed on the integrated circuit substrate. The lower electrode layer of the MIM capacitor is electrically coupled to 10 the drain of the transistor. A third conductive interconnection layer may be formed on the second intermetal dielectric layer and the first conductive interconnection layer and the second conductive interconnection layer may electrically couple the upper electrode to the third interconnection layer. The device may further include a second transistor having a drain and a gate formed on the integrated circuit substrate, the 15 second transistor having a common source with the first transistor and the drain of the second transistor being electrically coupled to the third interconnection layer.

In further embodiments of the present invention integrated circuit memory devices and large scale integration (LSI) logic circuits are provided including an integrated circuit device having a MIM capacitor as described above.

20 In other embodiments of the present invention, methods are provided of manufacturing an integrated circuit device including a metal-insulator-metal (MIM) capacitor. A MIM capacitor, including a lower electrode, a dielectric layer and an upper electrode, is formed on an integrated circuit substrate. A first insulating layer is formed on the upper electrode of the MIM capacitor. At least one via hole is formed 25 in the first insulating layer extending to the upper electrode of the MIM capacitor. A landing pad type independent interconnection layer is formed in the at least one via hole in the first insulating layer. A second insulating layer is formed on the first insulating layer. At least one via hole is formed in the second insulating layer extending to the first insulating layer and at least partially exposing the landing pad 30 type independent interconnection layer. A second conductive interconnection layer is formed in the at least one via hole of the second insulating layer that electrically contacts the landing pad type independent interconnection layer. Forming the MIM capacitor may include forming the dielectric layer to have a thickness between the

upper and lower electrode greater than the thickness of the dielectric layer in other regions of the device.

Further embodiments of the present invention provide semiconductor devices including a MIM capacitor formed on a semiconductor substrate and having a lower electrode, a dielectric layer, and an upper electrode. A first intermetal dielectric (IMD) is formed on the upper and lower electrodes of the MIM capacitor and a first via hole is defined in the first IMD on the upper electrode of the MIM capacitor. A landing pad type independent interconnection layer is formed in the first via hole. A second IMD is formed to have a second via hole exposing the landing pad type independent interconnection layer formed on the MIM capacitor. An interconnection layer is formed in the second via hole to connect with the upper electrode of the MIM capacitor.

The lower electrode of the MIM capacitor may contact a drain formed in the semiconductor substrate. The upper electrode may be formed to completely cover the lower electrode.

In other embodiments of the present invention, the thickness of the dielectric layer formed under the upper electrode is greater than that of the dielectric layer formed at regions other than the region where the upper electrode is formed. An insulating pattern, which is formed of one of an oxide layer, a nitride layer, an FSG layer, an OSG layer, a SiC layer, or a combination thereof, may be formed on the upper electrode. The insulating pattern may not be formed in regions other than the region where the upper electrode is formed.

In further embodiments of the present invention, the first IMD includes a trench that has a diameter greater than the diameter of the first via hole and a depth that is smaller than the depth of the first via hole. The second IMD may also include a trench that has a diameter greater than the diameter of the second via hole and a depth that is smaller than the depth of the second via hole. The landing pad type independent interconnection layer may be formed to the same height as the first IMD. The landing pad type independent interconnection layer may include a plurality of interconnections that are separated from each other. The upper portion of the landing pad type independent interconnection layer may be wider than the lower portion thereof. Alternatively, the interconnection layer, which is connected to the upper electrode of the MIM capacitor, may be formed to the same height as the second IMD.

In other embodiments of the present invention, semiconductor devices are provided including a lower electrode of a MIM capacitor, which is formed on a semiconductor substrate and contacts an impurity region formed in the semiconductor substrate. A dielectric layer is formed on the lower electrode and an upper electrode 5 of the MIM capacitor is formed on the dielectric layer. An insulating pattern may be formed on the upper electrode of the MIM capacitor. A first IMD is formed on the insulating pattern and a first via hole is defined in the first IMD in the region of the upper electrode. A landing pad type independent interconnection layer is formed in the first via hole. A second IMD is formed with a second via hole that exposes the 10 landing pad type independent interconnection layer formed on the MIM capacitor. An interconnection layer is formed in the second via hole that connects with the upper electrode of the MIM capacitor.

In further embodiments of the present invention semiconductor devices are provided including a lower electrode of a MIM capacitor formed on a semiconductor 15 substrate and contacting an impurity region formed in the semiconductor substrate. A dielectric layer is formed on the semiconductor substrate including the lower electrode. The thickness of the dielectric layer formed on the lower electrode is greater than that of the dielectric layer formed at regions other than the region where the lower electrode is formed. An upper electrode of the MIM capacitor is formed at 20 the region where the dielectric layer is thick. An insulating pattern is formed on the upper electrode of the MIM capacitor. A first IMD is formed on the insulating pattern and a first via hole is defined in the first IMD on the upper electrode of the MIM capacitor. A landing pad type independent interconnection layer is formed in the first via hole. A second IMD is formed to have a second via hole exposing the landing pad 25 type independent interconnection layer formed on the MIM capacitor. An interconnection layer is formed in the second via hole to connect with the upper electrode via the landing pad type independent interconnection layer.

In other embodiments of the present invention, semiconductor devices are provided including a lower electrode of a MIM capacitor formed on a semiconductor 30 substrate and contacting an impurity region formed in the semiconductor substrate. A dielectric layer is formed on the semiconductor substrate including the lower electrode and includes regions having thicknesses different from each other. A thick portion of the dielectric layer is disposed on the lower electrode of the MIM capacitor. An upper

electrode of the MIM capacitor is formed to completely cover the lower electrode of the MIM capacitor. An insulating pattern is formed only on the upper electrode of the MIM capacitor. A first IMD is formed on the insulating pattern and a plurality of first via holes are defined in the first IMD on the insulating pattern. A plurality of landing pad type independent interconnection layers are formed in the first via hole. A second IMD is formed to have a plurality of via holes exposing the plurality of landing pad type independent interconnection layers formed on the MIM capacitor. An interconnection layer is formed in the plurality of via holes to connect with the upper electrode of the MIM capacitor via the plurality of landing pad type independent 5 interconnection layers.

10

BRIEF DESCRIPTION OF THE DRAWINGS

Other features of the present invention will be more readily understood from the following detailed description of the invention when read in conjunction with the 15 accompanying drawings, in which:

FIG. 1 is a cross-sectional diagram illustrating an integrated circuit device including a MIM capacitor according to the prior art;

FIG. 2 is a graph illustrating the results of a simulation of parasitic capacitance for different thicknesses of an insulating layer for an integrated circuit 20 device including MIM capacitors according to the prior art;

FIG. 3 is a cross-sectional diagram illustrating an integrated circuit device including a MIM capacitor according to some embodiments of the present invention; and

FIGS. 4 through 10 are cross-sectional diagrams illustrating manufacturing of 25 the device of **FIG. 3** according to some embodiments of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

The present invention now will be described more fully hereinafter with reference to the accompanying drawings, in which typical embodiments of the 30 invention are shown. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art.

In the drawings, the relative sizes and shapes of regions may be exaggerated for clarity. It will be understood that when an element such as a layer, region or substrate is referred to as being "on" another element, it can be directly on the other element or intervening elements may also be present. In contrast, when an element is referred to
5 as being "directly on" another element, there are no intervening elements present. Moreover, each embodiment described and illustrated herein includes its complementary conductivity type embodiment as well. Terms used herein are to be given their ordinary meaning unless explicitly defined otherwise herein.

Integrated circuit devices and methods for forming such devices in accordance
10 with embodiments of the present invention will now be described with reference to
FIGs. 3-10. **FIG. 3** is a cross-sectional diagram illustrating an integrated circuit (semiconductor) device including a MIM capacitor according to some embodiments of the present invention. As shown in **FIG. 3**, the integrated circuit device includes a trench isolation region **103** and an active region **105** formed in an integrated circuit substrate **101**. The integrated circuit substrate **101** may be, for example, a silicon substrate.
15

The active region **105** includes a pair of transistors having a common source region. A first transistor includes a gate **109a**, a source **111**, a drain **113a** and a gate insulating layer **107**. The source **111** and drain **113a** may be impurity regions formed,
20 for example, by implanting impurity ions in the integrated circuit substrate **101**. The second transistor includes a gate **109b**, a drain **113b**, the source **111** and the gate insulating layer **107**.

A conductive pattern **119** defines contacts to the respective drains **113a**, **113b** via contact holes **117** in a first insulating layer **115**. A second insulating layer **123** and a third insulating layer **125** are formed on the conductive pattern **119** and first insulating layer **115**. First via holes **121** and a first trench **122** are formed in the second insulating layer **123** and the third insulating layer **125**. A lower electrode **127** of a MIM capacitor is formed in the second insulating layer **123** and the third insulating layer **125**. The lower electrode **127** is coupled to the drain **113a** through the
25 lower electrode **127** and conductive pattern **119** formed on via hole **121**, the trench **122** and the contact hole **117**. For the embodiments illustrated in **FIG. 3**, where only one of the transistors is coupled to a capacitor, a first interconnection layer **129** is

formed in the second insulating layer 123 and the third insulating layer 125 to provide a contact to the drain 113b through the conductive pattern 119 and the first interconnection layer 129 formed on the first trench 122, the first via hole 121 and the contact hole 117. However, it is to be understood that, in alternative embodiments, a 5 MIM capacitor may be formed coupled to the drain 113b in substantially the same manner as will be described with reference to the MIM capacitor coupled to the drain 113a.

A dielectric layer 131 is positioned between the lower electrode 127 and an upper electrode 133 of the MIM capacitor. An insulating intermetal dielectric layer or 10 first IMD 141 is formed on the upper electrode 133. The first IMD 141 includes a fourth insulating pattern 135, a fifth insulating layer 137, and a sixth insulating layer 139. In various embodiments of the present invention, the total thickness of the first IMD 141 is from about 0.01 micrometers (μm) to about 2.0 μm . In further 15 embodiments of the present invention, the total thickness of the first IMD is from about 0.1 μm to about 0.8 μm . It is further to be understood that the fourth insulating pattern 135, the fifth insulating layer 137 and the sixth insulating layer 139 may be formed as a single insulating layer. Furthermore, the first IMD 141 may include only the fifth insulating layer 137 and the sixth insulating layer 139 in embodiments of the present invention not including the insulating pattern 135.

20 Second via holes 143 and second trenches 144 are provided in the first IMD 141 that extend to and at least partially expose the upper electrode 133 of the MIM capacitor and the first interconnection layer 129. A first conductive interconnection layer, shown in FIG. 3 as a landing pad type independent interconnection layer 145, and a second interconnection layer 149 are provided in the second via holes 143 and 25 the second trenches 144.

In particular embodiments of the present invention, a plurality of second 30 trenches 144 and a plurality of second via holes 143 are formed on the MIM capacitor and extending to the upper electrode 133. The landing pad type independent interconnection layer 145 in the first IMD 141 thereby provides a plurality of contacts to the upper electrode 133. In various embodiments of the present invention, the width of the landing pad type independent interconnection layer 145 may be equal to or less than that of the lower electrode 127 of the MIM capacitor, for example, 200 μm

or less. As shown in **FIG. 3**, the landing pad type independent interconnection layer **145** may also have an upper width greater than its lower width. Furthermore, as shown in the embodiments of **FIG. 3** where a plurality of second trenches **144** and second via holes **143** are provided on the upper electrode **133**, the landing pad type 5 independent interconnection layer **145** may include a plurality of interconnections which are separated from each other.

As further illustrated in **FIG. 3**, a further insulating intermetal dielectric layer or second IMD **155** is formed on the landing pad type independent interconnection layer **145**, the second interconnection layer **149** and the first IMD **141**. The second 10 IMD **155** includes a seventh insulating layer **151** and an eighth insulating layer **153**. In some embodiments of the present invention, the total thickness of the second IMD **155** is from about $0.01\mu\text{m}$ to about $2.0\mu\text{m}$. In further embodiments of the present invention, the total thickness of the second IMD **155** is from about $0.1\mu\text{m}$ to about 15 $0.8\mu\text{m}$. The seventh and eighth insulating layers **151** and **153** may be formed as a single layer or a multiple layer.

A third via hole **157** in the second IMD **155** extends to the first IMD **141** and at least partially exposes the landing pad type independent interconnection layer **145** and the second interconnection layer **149**. In addition, a third trench **159** for forming a third interconnection layer **161** are formed in the second IMD **155**. For the 20 embodiments illustrated in **FIG. 3**, a plurality of third via holes **157** are formed in the second IMD **155** over the upper electrode **133** and the landing pad type independent interconnection layer **145**. The third interconnection layer **161** is formed in the third via holes **157** and the third trench **159**. The third interconnection layer **161**, in particular embodiments of the present invention, provides power to the upper 25 electrode **133** of the MIM capacitor.

For the embodiments illustrated in **FIG. 3**, the landing pad type independent interconnection layer **145** is used as a contact plug that connects the upper electrode **133** of the MIM capacitor with the third interconnection layer **161**. Thus, a thick insulating layer, as compared to the conventional device of **FIG. 1**, including the first 30 and second IMDs **141** and **155**, is disposed between the lower electrode **131** of the MIM capacitor and the third interconnection layer **161**. As a result, more stable capacitance characteristics may be provided for the MIM capacitor.

Methods for manufacturing the integrated circuit device of **FIG. 3** according to embodiments of the present invention will now be described with reference to the cross-sectional diagrams of **FIGS. 4** through **10**. Referring first to **FIG. 4**, a trench isolation region **103** is formed in an integrated circuit substrate **101**, such as a silicon substrate, for example, using a shallow trench isolation (STI) technique. A gate insulating layer **107** is formed on the integrated circuit substrate **101**. A first gate **109a** and a second gate **109b** are formed on the gate insulating layer **107**. The gates **109a**, **109b** may be, as illustrated in **FIG. 4**, a multiple layer formed, for example, of a polysilicon layer and a silicide layer formed thereon. A common source **111** and respective drain **113a**, **113b** are formed adjacent the gates **109a**, **109b** using, for example, an ion implantation process.

A first insulating layer **115** is formed on the integrated circuit substrate **101** in the region where the gates **109a**, **109b**, the source **111** and the drains **113a**, **113b** are formed. The first insulating layer **115** may be formed, for example, of one of a plasma enhanced (PE) oxide layer, a high density plasma (HDP) oxide layer, a plasma enhanced TEOS (PE-TEOS) oxide layer, a high temperature oxide (HTO) layer, a BPSG layer, a flowable oxide (FOX) layer and/or a combination thereof. The first insulating layer **115** may be formed to a thickness of about $0.01\mu\text{m}$ to about $2\mu\text{m}$. In particular embodiments of the present invention, the first insulating layer **115** is formed to a thickness of about $0.4\mu\text{m}$ to about $1.0\mu\text{m}$.

A contact hole **117** to each drain **113a**, **113b** is formed in the first insulating layer **115** using, for example, a photolithographic process. A conductive layer may then be formed on the entire surface of the integrated circuit substrate **101** in the region where the contact hole(s) **117** are formed. A conductive pattern **119** is formed to contact the respective drains **113a**, **113b** via the contact hole(s) **117**, for example, using ordinary photolithographic and/or etching processes.

A second insulating layer **123** and a third insulating layer **125** are sequentially formed on the surface of the integrated circuit substrate **101** in the region where the conductive pattern **119** is formed. The second and third insulating layers **123** and **125** may be formed of oxide layers or other suitable insulating layers, such as a fluorine-doped silicate glass (FSG) layer, an organo silicate glass (OSG) layer and/or an inorganic polymer layer. The second and third insulating layers **123** and **125** may be

formed using, for example, chemical vapor deposition (CVD), physical vapor deposition (PVD), atomic layer deposition (ALD), or spin coating. The second and third insulating layers 123 and 125 may be formed to a thickness of about 0.01 μm to about 2 μm and, for some embodiments of the present invention, to about 0.3 μm to 5 about 0.8 μm .

A lower electrode 127 and a first interconnection layer 129 may be simultaneously formed in first via hole(s) 121 and first trenches 122 formed in the second and third insulating layers 123 and 125, for example, using a dual damascene process. The dual damascene process is generally classified into a "via first" type dual 10 damascene process and a "trench first" type dual damascene process.

The "via first" dual damascene type process generally includes forming the first via hole(s) 121 in the second and third insulating layers 123 and 125 and then forming the first trench(es) 122 in the third insulating layer 125. In contrast, the "trench first" dual damascene type process generally includes forming the first 15 trench(es) 122 in the third insulating layer 125 and then forming the first via hole(s) 121 in the second insulating layer 123. A conductive layer for the first interconnection layer 129 and the lower electrode 127 of the MIM capacitor is then deposited on the surface of the semiconductor substrate 101 so as to fill the first via hole(s) 121 and first trench(es) 122. The entire deposited conductive layer, except for 20 the portion filling the first via hole(s) 121 and the first trench(es) 122 is then removed using a conventional chemical mechanical planarization or polishing (CMP). As a result, the lower electrode 127 of the MIM capacitor and the first interconnection layer 129 may be simultaneously formed.

The lower electrode 127 of the MIM capacitor and the first interconnection 25 layer 129 may be formed using known methods other than the dual damascene process described above. For example, after the first via hole(s) 121 are formed, a contact plug may be formed to fill the first via hole(s) 121. The first trench(es) 122 may then be formed and a conductive layer may be deposited to form the first interconnection layer and the lower electrode. The conductive layer may then be polished using, for 30 example, chemical mechanical planarization or polishing(CMP).

The second and third insulating layers 123 and 125 may be either a single layer or a multiple layer as illustrated in FIG. 4. The second and third insulating layers 123

and **125** may be formed using a single step or a multiple step fabrication process. The first trench(es) **122** may be formed in the third insulating layer **125** and/or the first trench(es) **122** may penetrate into the second insulating layer **123**.

The conductive layer used for the lower electrode **127** of the MIM capacitor and/or the first interconnection layer **129** may be formed of a metal such as copper (Cu), aluminium (Al), titanium (Ti), tantalum (Ta), titanium nitride (TiN), tantalum nitride (TaN), tantalum silicon nitride (TaSiN), titanium silicon nitride (TiSiN), tungsten nitride (WN) or tungsten silicon nitride (WSiN). The conductive layer used for the lower electrode **127** and/or the first interconnection layer **129** may be formed, for example, using CVD, PVD or electroplating. The conductive layer used for the lower electrode **127** and/or the first interconnection layer **129** may be formed to a thickness of about $0.001\mu\text{m}$ to about $2\mu\text{m}$ and, for particular embodiments of the present invention, to a thickness of about $0.05\mu\text{m}$ to about $0.8\mu\text{m}$.

A dielectric pattern **131**, an upper electrode **133** of the MIM capacitor and a fourth insulating pattern **135** are sequentially formed on the integrated circuit substrate **101** in the region where the lower electrode **127** is formed. The dielectric pattern **131** provides the a dielectric layer of the MIM capacitor and is sequentially formed with a conductive layer for the upper electrode **133** and a fourth insulating layer for the fourth insulating pattern **135** on the lower electrode **127**, the third insulating layer **125** and the first interconnection layer **129**. The sequentially formed layers are patterned using, for example, photolithographic and etching processes, to complete formation of the dielectric pattern **131**, the upper electrode **133** and the fourth insulating pattern **135**.

The patterning process may be performed so that the thickness of the remaining dielectric pattern **131** is about $0.001\mu\text{m}$ to about $1\mu\text{m}$ and, for particular embodiments of the present invention, a thickness of about $0.01\mu\text{m}$ to about $0.1\mu\text{m}$. Such a thickness range may reduce and/or minimize out diffusion of the material used for the lower electrode **127**.

As a result of the processes described with reference to FIG. 4, a MIM capacitor including the lower electrode **127**, the dielectric pattern **131** and the upper electrode **133** is formed on the integrated circuit substrate **101**.

The dielectric pattern **131** may be, for example, a nitride layer, an oxide layer, a silicon carbide (SiC) layer, a silicon oxynitride (SiON) layer, a silicon carbinitride (SiCN) layer, a silicon oxyfluoride (SiOF) layer, a silicon carbohydride (SiOH) layer, a hafnium oxide (HfO₂) layer and/or an aluminum oxide (Al₂O₃) layer. The dielectric pattern **131** may be formed using a process such as CVD, PVD, or ALD. In some embodiments of the present invention, the dielectric pattern **131** is formed to a thickness of about 0.001μm to about 1μm. In other embodiments, the dielectric pattern **131** is formed to a thickness of about 0.01μm to about 0.5μm.

The upper electrode **133** is formed of a conductive layer. The conductive layer of the upper electrode maybe formed, for example, of a metal such as copper (Cu), tantalum nitride (TaN), aluminum (Al), titanium (Ti), tantalum (Ta), titanium nitride (TiN), tantalum silicon nitride (TaSiN), titanium silicon nitride (TiSiN), tungsten nitride (WN) and/or tungsten silicon nitride (WSiN) using, for example, CVD, PVD and/or electroplating. The conductive layer of the upper electrode may be formed to a thickness of about 0.001μm to about 2μm and, in particular embodiments, to a thickness of about 0.05μm to about 0.8μm.

The fourth insulating pattern **135** may be formed of an oxide layer, a nitride layer and other insulating layers, such as an FSG layer, an OSG layer and/or an SiC layer (or a combination thereof) using, for example, CVD, PVD, or ALD. The fourth insulating pattern **135** may be formed to a thickness of about 0.001μm to about 1μm and, in particular embodiments, to a thickness of about 0.01μm to about 0.5μm. The fourth insulating pattern **135** may be used to suppress generation of a polymer during a subsequent etching process (such as forming a contact).

A fifth insulating layer **137** and a sixth insulating layer **139** are formed on the surface of the integrated circuit substrate **101** in the region where the MIM capacitor is formed. As a result, a first IMD **141** including the fourth insulating pattern **135**, the fifth insulating layer **137** and the sixth insulating layer **139** is formed on the upper electrode **133** and on the first interconnection layer **129**. The fifth and sixth insulating layers **137** and **139** may be formed of an oxide layer, an SiC layer, an SiON layer, an SiCN layer, an SiOF layer, an SiOH layer, an HfO₂ layer, a zirconium oxide (ZrO₂) layer and/or an Al₂O₃ layer using, for example, CVD, PVD, or ALD. The fifth and sixth insulating layers **137** and **139** may be formed to a thickness of about 0.1μm to about 2μm and, in particular embodiments, to a thickness of about 0.3μm to about

0.8 μ m. The fifth and sixth insulating layers 137 and 139 may be formed as a single layer or as multiple layers through a plurality of steps or in a single step.

Referring now to FIGS. 5 through 7, a second via hole 143, a second trench 144, a landing pad type independent interconnection layer 145, and a second interconnection layer 149 are formed, for example, using the dual damascene process as described above. However, the second via hole 143, the second trench 144, the landing pad type independent interconnection layer 145 and the second interconnection layer 149 may be formed using other known methods as an alternative to the dual damascene process. For example, after the fifth insulating layer 137 is formed, the second via hole 143 may be formed. A contact plug may then be formed to fill the second via hole 143. The sixth insulating layer 139 and the second trench 144 may then be formed. A metal layer for the second interconnection layer 149 and to complete the landing pad type independent interconnection layer 145 may then be deposited. Finally, the metal layer may be polished using, for example, CMP.

FIGS. 5 through 7 particularly illustrate a method of forming the second via hole 143, the second trench 144, the landing pad type independent interconnection layer 145 and the second interconnection layer 149 using the "via first" dual damascene process. The second via hole 143, the second trench 144, the landing pad type independent interconnection layer 145 and the second interconnection layer 149 may also be formed using the "trench first" dual damascene process.

As shown in FIG. 5, the sixth insulating layer 139, the fifth insulating layer 137 and the fourth insulating pattern 135, which constitute the first IMD 141, are patterned using photolithographic and etching processes to form the second via hole(s) 143. The second via hole(s) 143 expose the upper electrode 133 of the MIM capacitor as well as the first interconnection layer 129.

As shown in FIG. 6, a portion of the first IMD 141 formed on the MIM capacitor, i.e. the sixth insulating layer 139, is selectively etched using, for example, photolithographic and etching processes, to form second trench(es) 144 in the region where the second interconnection layer 149 and the landing pad type independent interconnection layer 145 will be formed. The second trench(es) 144 in the region where the landing pad type independent interconnection layer 145 will be formed are formed in the first IMD 141 formed on the MIM capacitor, i.e. the sixth insulating

layer **139**. The second trench(es) **144**, as illustrated in **FIG. 6**, have a greater diameter than a diameter of the second via hole(s) **143**.

Referring now to **FIG. 7**, the landing pad type independent interconnection layer **145** and second interconnection layer **149** are formed to fill the second via hole(s) **143** and second trench(es) **144**. The landing pad type independent interconnection layer **145** is formed in the second via hole(s) **143** and second trench(es) **144**.

In some embodiments of the present invention, forming of the landing pad type independent interconnection layer **145** includes forming a conductive layer on the entire surface of the integrated circuit substrate **101** to fill the second via hole(s) **143** and the second trench(es) **144**. The conductive layer is then planarized using, for example, CMP. As a result, the top surfaces of the landing pad type independent interconnection layer **145** and the second interconnection layer **149** may be formed to the same height as the sixth insulating layer **139**. The width of the landing pad type independent interconnection layer **145** in some embodiments of the present invention is less than that of the lower electrode **127** of the MIM capacitor, for example, 200 μm or less. The width at the top of the landing pad type independent interconnection layer **145** may be greater than that at the bottom thereof. The landing pad type independent interconnection layer **145** may be formed of a plurality of interconnection layers in via holes and trenches that are separated from each other.

The landing pad type independent interconnection layer **145** and the second interconnection layer **149** may be formed of copper (Cu), aluminium (Al), titanium (Ti), tantalum (Ta), titanium nitride (TiN), tantalum nitride (TaN), tantalum silicon nitride (TaSiN), titanium silicon nitride (TiSiN), tungsten nitride (WN) and/or tungsten silicon nitride (WSiN) and may be formed using, for example, CVD, PVD or electroplating. The landing pad type independent interconnection layer **145** and the second interconnection layer **149** may be formed to a thickness of about 0.1 μm to about 2 μm and, in particular embodiments, to a thickness of about 0.05 μm to about 0.8 μm .

As shown in **FIG. 8**, a seventh insulating layer **151** and an eighth insulating layer **153**, which constitute the second IMD **155**, are formed on the surface of the semiconductor substrate **101** in the region where the MIM capacitor is formed. In

other words, the seventh insulating layer 151 and the eighth insulating layer 153 are formed on the landing pad type independent interconnection layer 145 and the first IMD 141. The second IMD 155 may be formed through a single step process or using a plurality of steps and may be formed as a single layer or a multiple layer structure 5 including subsequent layers.

The seventh and eighth insulating layers 151 and 153 may be formed of oxide layers or other insulating layers such as a SiC layer, a SiON layer, a SiCN layer, a SiOF layer, a SiOH layer, a HfO₂ layer, a ZrO₂ layer, or an Al₂O₃ layer. The seventh and eight insulating layers 151 and 153 may be formed using, for example, CVD, 10 PVD, or ALD. The seventh and eight insulating layers 151 and 153 may be formed to a thickness of about 0.001 μm to about 1 μm and, in particular embodiments, to a thickness of about 0.01 μm to about 0.1 μm. Alternatively, the seventh and eighth insulating layers 151 and 153 may be formed of oxide layers or other insulating layers such as an FSG layer, an OSG layer and/or an inorganic polymer layer using, for 15 example, CVD or spin coating. The seventh and eighth insulating layers 151 and 153 in such embodiments may be formed to a thickness of about 0.01 μm to about 2 μm and, in particular embodiments, to a thickness of about 0.1 μm to about 0.8 μm.

As seen in FIG. 10, third via hole(s) 157, third trench(es) 159 and a third interconnection layer 161 (see FIG. 3) are formed, for example, using the dual 20 damascene process. The third via hole(s) 157, the third trench(es) 153 and the third interconnection layer 161 may also be formed using known methods other than the dual damascene process. For example, after the seventh insulating layer 151 is formed, the third via hole(s) 157 may be formed. A contact plug may then be formed to fill the third via hole(s) 157. The eighth insulating layer 153 and the third trench(es) 159 may then be formed. A metal layer for the third interconnection layer 25 may then be deposited. Finally, the metal layer may be polished, for example, using CMP.

FIGS. 9 and 10 particularly illustrate a method of forming the third via hole 157, the third trench 159 and the third interconnection layer 161 using the "via first" 30 dual damascene process. However, as noted above, it is also possible to form the third via hole(s) 157, the third trench(es) 159 and the third interconnection layer 161 using the "trench first" dual damascene process or other processes. As shown in FIG. 9, the

seventh and eight insulating layers, which constitute the second IMD 155, are patterned using, for example, photolithographic and etching processes, to form the third via hole(s) 157. The third via hole(s) 157 expose the landing pad type independent interconnection layer 145 and the second interconnection layer 149.

5 Referring now to **FIG. 10**, a portion of the second IMD 155, for example, the eighth insulating layer 153, is selectively etched, for example, using photolithographic and etching processes, to form the third trench(es) 159 in the region where the third interconnection layer 161 will be formed. The third trench 159 is formed in the second IMD 155, for example, in the eighth insulating layer 153, and has a greater diameter than the third via hole(s) 157.
10

As illustrated in **FIG. 3**, the third interconnection layer 161 is filled into the third via hole(s) 157 and the third trench(es) 159. Forming of the third interconnection layer 161 may include forming a conductive layer on the entire surface of the semiconductor substrate 101 to fill the third via hole(s) 157 and the 15 third trench(es) 159, followed by planarizing the conductive layer using, for example, CMP. As a result, the top surface of the third interconnection layer 161 may be formed to the same height as that of the eighth insulating layer 153 in the region including the second IMD 155. In some embodiments of the present invention, as illustrated in **FIG. 10**, a plurality of third via holes 157 are provided through which 20 the third interconnection layer 161 contacts the landing pad type independent interconnection layer 145.

The third interconnection layer 161 may be formed of a metal such as copper (Cu), aluminium (Al), titanium (Ti), tantalum (Ta), titanium nitride (TiN), tantalum nitride (TaN), tantalum silicon nitride (TaSiN), titanium silicon nitride (TiSiN), 25 tungsten nitride (WN) and/or tungsten silicon nitride (WsiN) using, for example, CVD, PVD or electroplating. The third interconnection layer 161 may be formed to a thickness of about 0.01 μm to about 2 μm and, for particular embodiments, to a thickness of about 0.1 μm to about 0.8 μm .

While the embodiments of the present invention have been described with 30 reference to a method of forming interconnections using the dual damascene process, the method should not be limited to the embodiments set forth herein and interconnections may also be formed using typical photolithographic and etching

processes. Further, it is also possible to omit the step of forming the second via hole and form the second via hole by simultaneously etching the first and second IMDs during the step of forming the third via hole. In addition, while the present invention has been described with reference to a MIM capacitor coupled to a transistor drain 5 sharing a common source with another transistor drain that is not coupled to a capacitor, the present invention also includes embodiments in which each drain is coupled to a capacitor or in which only a single drain is provided without an associated drain of a transistor sharing a common source. Moreover, while the present invention has generally been described above with no diffusion barrier layers and/or 10 adhesion layers under and/or on the metal layers, diffusion barrier layers and/or adhesion layers can be used to reduce or prevent diffusion of atoms used for forming metal layers and to enhance adhesion of metal layers.

As described above, according to some embodiments of the present invention, the upper electrode of a MIM capacitor is connected to an upper interconnection layer 15 via a landing pad type independent interconnection layer allowing for a thicker IMD layer. Such a structure may limit the adverse affect of parasitic capacitance on the characteristics of the MIM capacitor. As a result, MIM capacitors with stable characteristics may be obtained.

It should be noted that many variations and modifications may be made to the 20 embodiments described above without substantially departing from the principles of the present invention. All such variations and modifications are intended to be included herein within the scope of the present invention, as set forth in the following claims.
